DESCRIPTION

Method keywords
- toxicology
- in vitro
- drug testing
- Intracellular lipids
- phospholipids
- Phospholipidosis
- amiodarone

Scientific area keywords
- hepatic differentiation
Hepatotoxicity
skin-derived precursors
skin stem cells

**Method description**

Drug-induced phospholipidosis (DIPL) is a metabolic disorder characterized by an excessive intracellular accumulation of phospholipids caused by cationic drugs. Hepatic cells derived from human skin are evaluated as an *in vitro* model to investigate DIPL and its mechanisms. Human skin stem cells (hSKP) are isolated, under informed consent, from human circumcised foreskin samples of young boys and hSKP are differentiated for 24 days to obtain hepatic-like cells (hSKP-HPC), as previously described. hSKP-HPC are exposed to amiodarone, a drug known to induce phospholipidosis in humans. Upon exposure to amiodarone for 24, 48, 72h, hSKP-HPC retain intracellular phospholipids, form lamellar bodies and show alterations at the gene expression level. Overall, these findings prove that hSKP-HPC might contribute to setting up an accurate *in vitro* platform for hepatotoxicity testing.

**Lab equipment**

Laminar air flow;
Flow cytometry;
Transmission electron microscopy;
Reverse transcriptase-polymerase chain reaction (qPCR) reagents.

**Method status**

History of use

**PROS, CONS & FUTURE POTENTIAL**

**Advantages**

Applicability of hSKP-HPC for the quick assessment of drug-induced phospholipidosis *in vitro*;
Different human donors can be tested to assess toxicity.

**Future & Other applications**
In vitro toxicity testing in the drug development process
