DESCRIPTION

Method keywords

Fish embryo
Fertilised zebrafish eggs
Somite formation
Fertilisation rate
Reproducibility
Lethality
Method description

The method has been fully described in OECD TG 236 and is intended to determine the acute or lethal toxicity of chemicals on embryonic stages of fish (*Danio rerio*). Newly fertilized zebrafish eggs are exposed to the test chemical for a period of 96 hrs. Every 24 hrs. Twenty embryos (one embryo per well) are exposed to the chemical tested at each concentration level. The test includes five increasing concentrations of the chemical tested and a control. Every 24 hours, four apical observations are recorded as indicators of lethality: (i) coagulation of fertilised eggs, (ii) lack of somite formation, (iii) lack of detachment of the tail-bud from the yolk sac, and (iv) lack of heartbeat. At the end of the exposure period, acute toxicity is determined based on a positive outcome in any of the four apical observations recorded, and the LC50 is calculated. The test report also includes a number of other important information elements related to the conduct of the test, in particular: the concentration of dissolved oxygen, pH, total hardness, temperature and conductivity of solutions, measured concentrations of the chemical tested, and whether the validity criteria of the test were met.

Lab equipment
- Fish tanks made of chemically inert material and of a suitable capacity;
- Inverted microscope or binocular with a capacity of at least 80-fold magnification;
- Test chambers (glass or polystyrene);
- Incubator or air-conditioned room with controlled temperature;
- Spawn trap.

**Method status**

Published in peer reviewed journal
Validated by an external party (e.g. OECD, EURL ECVAM,...)

**PROS, CONS & FUTURE POTENTIAL**

**Advantages**

- Fast and cost-effective;
- The FET-test has been successfully applied to a wide range of substances exhibiting diverse modes of action, solubility, volatility, and hydrophobicity.

**Challenges**

- If the method is used for the testing of a mixture, its composition should, as far as possible, be characterized. Before use for regulatory testing of a mixture, it should be considered whether it will provide acceptable results for the intended regulatory purpose.
- The metabolic capabilities of fish embryos are not always similar to that of juvenile or adult fish. For instance, the protoxicant allylalcohol has been missed in the FET.
- For substances with a molecular weight ≥3kDa, a very bulky molecular structure, and substances causing delayed hatch which might preclude or reduce the post-hatch exposure, embryos are not expected to be sensitive because of limited bioavailability of the substance, and other toxicity tests might be more appropriate.
- The use of solvents should be avoided, but may be required in some cases in order
to produce a suitably concentrated stock solution. Where a solvent is used to assist in stock solution preparation, its final concentration should not exceed 100 µl/L and should be the same in all test vessels. When a solvent is used, an additional solvent control is required. For more information see OECD TG nr. 236

Future & Other applications

The test can also be used for the selection and ranking of candidate chemicals during the development of new chemicals and products and in toxicology research.
